U.S. GEOLOGICAL SURVEY

Pollen Data for a 3-m.y. core record from
Tulelake, Siskiyou County, California

by

David P. Adam¹
and
Ginger L. Vagenas¹

Open-File Report 90-65

This report is preliminary and has not been reviewed for conformity with U.S. Geological Survey editorial standards (or with the North American Stratigraphic Code). Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

¹Menlo Park, California 94025

1990

I. Introduction

A sediment core spanning a stratigraphic interval of 334 m was collected in 1983 from a drill site at the western edge of the town of Tulelake, Siskiyou County, California (Figure 1). The core has been analysed in several ways, including analyses for pollen, diatoms, tephra, paleomagnetism, and geochemistry (Adam and others, 1989). This report presents pollen counts for the samples completed as of September, 1989.

II. Site description

The town of Tulelake lies on the reclaimed bed of Tule Lake, which is part of an ancient lacustrine system that included both Tule Lake and Lower Klamath Lake. We located the drill site near the deep (815 m) water well drilled by the town of Tulelake because the driller's log for that well (Hotchkiss, 1968) indicated that a deep sedimentary section was present.

III. Methods

Five holes were drilled using a combination of Pitcher Barrel coring from the surface to a depth of 47.25 m (hole 1), 2.875-inch (73 mm) wireline equipment from the surface to a depth of 234.75 m, and 2.25-inch (57 mm) wireline equipment below 234.75 m (hole 2), and 2.25-inch (57 mm) wireline equipment at selected depths above 77.74 m in order to bridge gaps in recovery for the first two holes (holes 3, 4, and 5). The five holes were drilled within a small area, but only one extended below a depth of 80 m. Drilling stopped at a depth of 334 m when the drill stem became too heavy to lift safely with our equipment.

Pollen samples were removed from the cores both in the field and in subsequent laboratory sampling. Processing was done using standard techniques for Quaternary pollen, including HF digestion, acetylation, dehydration using tertiary butyl alcohol, and mounting in silicone oil. No attempt was made to use tracer pollen grains to determine pollen concentrations, because (1) much of the deeper sediment was rather hard and brittle, and volumetric sampling would have been difficult, and (2) we expected that much of the section would lack the detailed time control that would be needed for such work.

At least 200 fossil pollen grains were counted to estimate the percentages of taxa present. Algae were counted outside the pollen sum. When algae were much more abundant than pollen, the counts for all algae were recorded when the most common algal type reached a count of 100, along with the number of pollen grains recorded up to that point. Estimates of the numbers of the various algae were then calculated using the formula

$$N_{est} = N_{observed} \times S_{pollen}/S_{algae} ,$$

where N_{est} is the estimated total number of a particular alga that would have been counted if counting had continued until the pollen sum was reached, $N_{observed}$ is the number of that alga counted when the algal counts were recorded, S_{pollen} is the total number of pollen grains counted, and S_{algae} is the number of pollen grains counted at the time the algal counts were recorded. This system produces rather wide confidence limits on the estimates of algal frequencies when algae are abundant, but it also requires counting fewer algae (Adam, 1988).

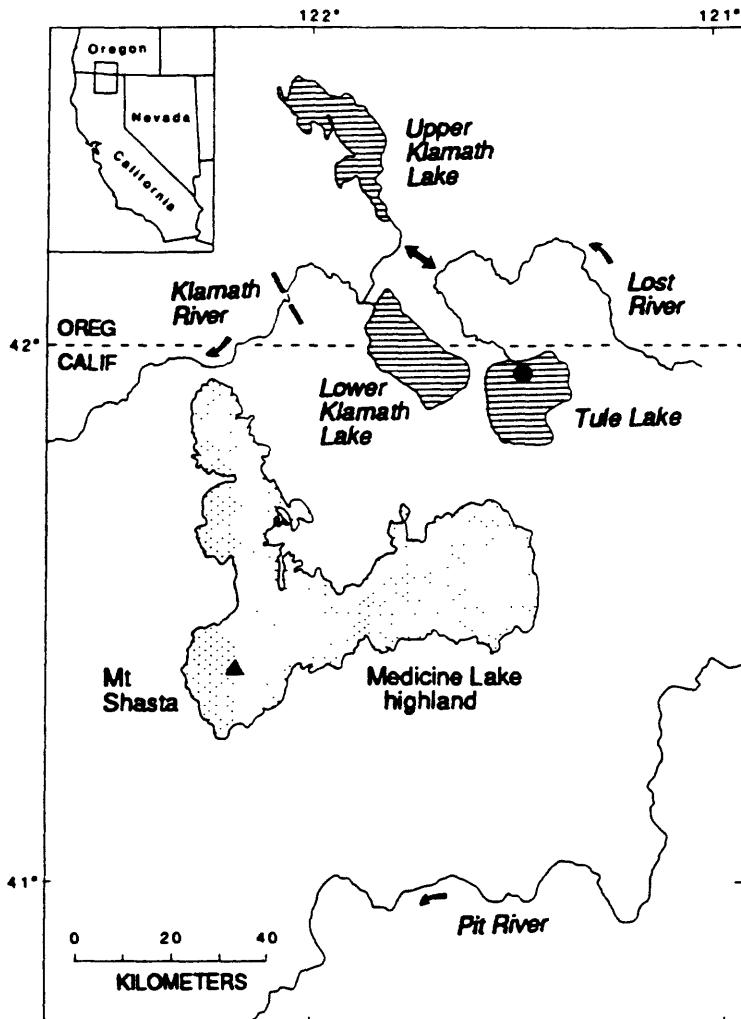

Figure 1.--Location map for the Tulelake core site (solid circle) and vicinity. Hachures indicate historic lakes; double-headed arrow indicates region of bi-directional flow between Lost and Klamath Rivers; dotted line across Klamath River indicates probable location of the sill over which the ancient lake system first spilled into the Klamath drainage. Lightly-shaded region indicates portions of the Medicine Lake Highlands and Mt. Shasta region with elevations in excess of 1525 m (5000 feet). From Adam and others (1989).

IV. Description of variables

The variables counted are listed in Appendix A. Pollen grains were identified using standard reference works and a reference collection of modern pollen grains. Additional information concerning particular types is given below. The variable type numbers are not consecutive because some numbers were assigned to composite groups; only the variables actually counted are discussed here. The rest of this section provides additional information about certain types that require it.

Pinus. *Pinus* (pine) grains were counted either as whole grains (Variable #1) or as halves (#2). The count recorded for Variable #2 is the number of halves, and is divided by 2 when adding whole plus broken pine to get the total pine contribution to the pollen sum. Pine grains of the *Haploxyylon* type were recorded when noted, but no attempt was made to classify each pine grain as either *Haploxyylon* or *Diploxyylon* type. *Haploxyylon*-type grains were not common.

TCT. The TCT category (Variable #6) includes pollen grains of the families Taxodiaceae, Cupressaceae, and Taxaceae. Most of the grains found probably represent either *Calocedrus decurrens* (Incense cedar) or *Juniperus occidentalis* (western juniper), but other forms may well be present, including *Cupressus*, *Chamaecyparis*, *Thuja*, and other species of *Juniperus*. Occasional grains of *Sequoia* type (probably true *Sequoia*, but possibly *Sequoiadendron*) were counted separately (Variable #11) when they could be identified by the presence of a papilla, but grains lacking a papilla were included in the TCT group.

Quercus and Quercoids. The genus *Quercus* (true oaks, variable #14) is rather variable in pollen morphology. Some grains do not clearly belong to *Quercus*, but are less unlike *Quercus* than they are unlike other forms. These uncertain forms are counted as "Quercoids" (Variable #15) to permit subsequent evaluation of the reliability of the oak pollen frequencies.

Lithocarpus/Chrysolepis. Pollen grains of *Lithocarpus* (tanbark oak) and *Chrysolepis* (*Castanopsis*) (chinquapin) were lumped together into a single category (Variable #17).

Artemesia and artemisioids. *Artemesia* (sagebrush, Variable #26) and artemisioids (Variable #27) were treated in the same way as the oaks.

Typha. Single grains were classified as *Typha/Sparganium* (cattail or burr-reed, Variable #43), whereas tetrad grains were counted separately (Variable #44).

Clear Lake Unknown A. This form is the same pollen type described at Clear Lake in the California Coast Ranges (Adam, 1988, Figure 9D). The grains are tetracolporate and reticulate, and resemble a small *Fraxinus* (ash) grain.

Tulelake Unknown A. This tricolporate pollen type is about 20 to 23 μm in diameter, with a double wall of uniform thickness and possible microreticulate sculpturing.

Tulelake Unknowns B-E. These types were counted separately, but each occurred only sporadically in only a few samples. They should be grouped with the other Unknowns (Variable #64) for future analyses.

Pediastrum, lettered types. The lettered types of the algal genus *Pediastrum* are those described at Clear Lake (Adam, 1988). Complete descriptions and illustrations may be found in that reference.

Appendix B - Pollen Counts

Counts are shown in normal type for variables that are included in the pollen sum and in italics for variables that are excluded from the pollen sum. A dash in the right-hand column for a type excluded from the pollen sum indicates that counting of that type continued until the pollen sum was reached.
